

频移和时移(位移)特性 设 $f(x)$ 的 Fourier 变换为 $\hat{f}(\lambda)$, 则 $\forall \lambda_0, x_0 \in (-\infty, +\infty)$, 有

$$\begin{aligned} F[f(x)e^{i\lambda_0 x}] &= \hat{f}(\lambda - \lambda_0), \\ F[f(x - x_0)] &= \hat{f}(\lambda)e^{-ix_0\lambda}. \end{aligned} \quad (4.1.6)$$

$$F\left[\int_{-\infty}^x f(\xi)d\xi\right] = \frac{1}{i\lambda} \hat{f}(\lambda). \quad (4.1.8)$$

卷积公式 设 $f(x), g(x)$ 的 Fourier 变换分别为 $\hat{f}(\lambda)$ 与 $\hat{g}(\lambda)$, 则它们的卷积函数

$$f(x) * g(x) = \int_{-\infty}^{+\infty} f(\xi)g(x - \xi)d\xi = \int_{-\infty}^{+\infty} f(x - \xi)g(\xi)d\xi \quad (4.1.9a)$$

的 Fourier 变换也存在, 且

$$F[f(x) * g(x)] = \hat{f}(\lambda)\hat{g}(\lambda). \quad (4.1.9b)$$

反射性 设 $f(x)$ 的 Fourier 变换为 $\hat{f}(\lambda)$, 则

$$F[\hat{f}(x)] = 2\pi f(-\lambda). \quad (4.1.10)$$

线性关系

$$L[\alpha f(t) + \beta g(t)] = \alpha L[f(t)] + \beta L[g(t)].$$

微分公式

$$L[f^{(n)}(t)] = p^n \bar{f}(p) - p^{n-1}f(+0) - p^{n-2}f'(+0) - \cdots - pf^{(n-2)}(+0) - f^{(n-1)}(+0). \quad (4.2.3)$$

与 Fourier 变换相同, Laplace 变换把求导运算变成了代数运算, 但是 n 阶导函数的 Laplace 变换需要知道相应的从 0 阶到 $n-1$ 阶导函数的初始值.

延退定理

$$L[f(t - \tau)] = L[f(t - \tau)H(t - \tau)] = e^{-p\tau} \bar{f}(p), \quad \tau > 0. \quad (4.2.4)$$

复频移公式 对任何一个复常数 p_0 , 有

$$L[f(t)e^{p_0 t}] = \bar{f}(p - p_0). \quad (4.2.5)$$

相似定理 对任意常数 $\alpha > 0$, 有

$$L[f(\alpha t)] = \frac{1}{\alpha} \bar{f}\left(\frac{p}{\alpha}\right). \quad (4.2.6)$$

$$L\left[\int_0^t f(\tau)d\tau\right] = \frac{\bar{f}(p)}{p}. \quad (4.2.7)$$

卷积公式

$$L[f(t) * g(t)] = \bar{f}(p) \cdot \bar{g}(p), \quad (4.2.8)$$

这里, 卷积

$$f(t) * g(t) = \int_{-\infty}^{+\infty} f(t - \tau)g(\tau)d\tau = \int_0^t f(t - \tau)g(\tau)d\tau. \quad (4.2.9)$$

像函数的微分公式

$$L[(-t)^n f(t)] = \bar{f}^{(n)}(p). \quad (4.2.10)$$

像函数的积分公式

$$L\left[\frac{f(t)}{t}\right] = \int_p^\infty \bar{f}(p)dp, \text{ 积分路径取在半平面 } \operatorname{Re} p > \sigma_0 \text{ 内.} \quad (4.2.11)$$

$$\delta(x) * f(x) = f(x),$$

$$\delta'(x) * f(x) = \delta(x) * f'(x) = f'(x),$$

$$\delta^{(n)}(x) * f(x) = \delta(x) * f^{(n)}(x) = f^{(n)}(x),$$

$$L(f(x) * g(x)) = (Lf) * g = f * Lg,$$

$$\int_{-\infty}^{+\infty} e^{\pm i\lambda x} dx = 2\pi\delta(\lambda),$$

$$\int_{-\infty}^{+\infty} \cos \lambda x dx = 2\pi\delta(\lambda),$$

$$\int_{-\infty}^{+\infty} x e^{-i\lambda x} dx = 2\pi i\delta'(\lambda).$$

$$\begin{cases} \frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial u}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2 u}{\partial \theta^2} = 0, & r < a, \\ u|_{r=a} = F(a \cos \theta, a \sin \theta) \stackrel{d}{=} f(\theta). \end{cases}$$

由叠加原理, 设

$$u(r, \theta) = \frac{A_0}{2} + \sum_{n=1}^{+\infty} \left(\frac{r}{a}\right)^n (A_n \cos n\theta + B_n \sin n\theta), \quad (2.1.12a)$$

代入边界条件 (2.1.8b) 式得

$$u(a, \theta) = \frac{A_0}{2} + \sum_{n=1}^{+\infty} (A_n \cos n\theta + B_n \sin n\theta) = f(\theta).$$

这是 $f(\theta)$ 在 $[0, 2\pi]$ 上的 Fourier 展开式, 故对 $n = 0, 1, 2, \dots$ 都有

$$A_n = \frac{1}{\pi} \int_0^{2\pi} f(\varphi) \cos n\varphi d\varphi, \quad (2.1.12b)$$

$$B_n = \frac{1}{\pi} \int_0^{2\pi} f(\varphi) \sin n\varphi d\varphi. \quad (2.1.12c)$$

过程可见, 圆外 ($r > a$) Laplace 方程有界解的一般形式为

$$u(r, \theta) = \frac{A_0}{2} + \sum_{n=1}^{+\infty} \left(\frac{a}{r}\right)^n (A_n \cos n\theta + B_n \sin n\theta), \quad r > a,$$

而环域 $a_1 < r < a_2$ 内 Laplace 方程解的一般形式则为

$$u(r, \theta) = \frac{C_0}{2} + \frac{D_0}{2} \ln r + \sum_{n=1}^{+\infty} (C_n r^n + D_n r^{-n}) (A_n \cos n\theta + B_n \sin n\theta),$$

$$\begin{cases} \frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial x^2} + f(t, x), & t > 0, -\infty < x < +\infty, \\ u|_{t=0} = \varphi(x), \quad \frac{\partial u}{\partial t}|_{t=0} = \psi(x) \end{cases}$$

$$\begin{aligned} u(t, x) &= \frac{1}{2} [\varphi(x - at) + \varphi(x + at)] + \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi)d\xi \\ &\quad + \frac{1}{2a} \int_0^t d\tau \int_{x-a(t-\tau)}^{x+a(t-\tau)} f(\tau, \xi)d\xi. \end{aligned}$$

欧拉方程: $r^2 R''(r) + p r R'(r) + q R(r) = 0$, p, q 为常数.

(1) 当 $r > 0$ 时, 作变量代换 $r = e^s$, 则 $s = \ln r$.

$$R'(r) = \frac{dR}{ds} \frac{ds}{dr} = \frac{1}{r} \frac{dR}{ds},$$

$$R''(r) = \frac{d}{dr} \left(\frac{1}{r} \frac{dR}{ds} \right) = -\frac{1}{r^2} \frac{dR}{ds} + \frac{1}{r} \frac{d^2 R}{ds^2} \frac{ds}{dr} = \frac{1}{r^2} \left(\frac{d^2 R}{ds^2} - \frac{dR}{ds} \right).$$

代入方程得 $\frac{d^2 R}{ds^2} + (p-1) \frac{dR}{ds} + qR = 0$. (*)

特征方程 $\mu^2 + (p-1)\mu + q = 0$, 求出特征值, 据此可写出方程(*)通解.

最后在通解中换回 $s = \ln r$.

先处理边界项.(P75)

解(I) 求仅满足边界条件(1.b)的任一函数 $v(x, t)$:

1) 若 a_1, a_2 不同时为 0 设 $v(x, t) = A(t)x + B(t)$;

2) $a_1 = a_2 = 0$ 时设 $v(x, t) = A(t)x^2 + B(t)x$.

将 $v(x, t)$ 代入边界条件(1.b), 求 $A(t), B(t)$, 得 $v(x, t)$.

(2) 令 $w = u - v$, 得 w 的定解问题(方程非齐次, 边界条件齐次);

(3) 线性分解, 用分离变量法和冲量原理分别求解, 合并得 $w(t, x)$, 或用 Fourier 展开法求出 $w(t, x)$;

(4) $u(t, x) = v(t, x) + w(t, x) = \dots$ #

本例中采用的 Fourier 展开法, 可用于一般的非齐次问题

$$\begin{cases} L_t u + L_x u = f(t, x), & t > 0, \quad a < x < b, \\ \left(\alpha_1 u - \beta_1 \frac{\partial u}{\partial x}\right)_{|x=a} = 0, \quad \left(\alpha_2 u + \beta_2 \frac{\partial u}{\partial x}\right)_{|x=b} = 0, \end{cases} \quad (2.3.9a)$$

$$u|_{t=0} = \varphi(x), \quad \frac{\partial u}{\partial t}|_{t=0} = \psi(x), \quad (2.3.9b)$$

其中, L_t, L_x 分别是关于 t, x 的二阶线性常微分算子.

第一步 分离变量法, 求出(2.3.9)式相应的齐次问题($f(t, x) = 0$)的固有值问题, 解出该问题相应的固有值 $\{\lambda_n\}$ 及固有函数系 $\{X_n(x)\}$.

第二步 据 S-L 定理判断 $\{X_n(x)\}$ 的完备性, 并将未知函数 $u(t, x)$ 及已知函数 $f(t, x), \varphi(x)$ 和 $\psi(x)$ 按固有函数系 $\{X_n(x)\}$ 作广义 Fourier 展开

$$u(t, x) = \sum_n T_n(t) X_n(x),$$

$$f(t, x) = \sum_n f_n(t) X_n(x),$$

$$\varphi(x) = \sum_n \varphi_n X_n(x), \quad \psi(x) = \sum_n \psi_n X_n(x),$$

代入方程(2.3.9a)及初始条件(2.3.9c)式, 利用 $L_x X_n(x) = -\lambda X_n(x)$, 得到未知函数 $u(t, x)$ 的广义 Fourier 系数 $T_n(t)$ 的初值问题

$$\begin{cases} L_t T_n(t) + \lambda_n T_n(t) = f_n(t), \\ T_n(0) = \varphi_n, \quad T'_n(0) = \psi_n. \end{cases}$$

第三步 解此初值问题, 确定 $T_n(t)$, 给出 $u(t, x)$ 的级数表达式.

背熟: $x J_0(x) = (x J_1(x))', \quad J_1(x) = -J_0'(x).$

• 当 $\Delta = a_{12}^2 - a_{11}a_{22} > 0$ 时, 称 (1.5.2) 为双曲型方程. ★★★

对(1.5.11), 令 $\begin{cases} t = \frac{1}{2}(\xi + \eta), \\ s = \frac{1}{2}(\xi - \eta), \end{cases}$ 由链式法则, (1.5.11) 可化为

$$\frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial s^2} + 4 \left(\tilde{B}_1 \frac{\partial u}{\partial t} + \tilde{B}_2 \frac{\partial u}{\partial s} + \tilde{B}_0 u \right) = 0. \quad \text{双曲型方程的另一标准型}$$

当 $\Delta = 0$ 时, 由特征方程 (1.5.9) 只能得一个一阶线性常微分方程. 不妨设 $a_{11} \neq 0$, 该方程为

$$\frac{dy}{dx} = \frac{a_{12}}{a_{11}},$$

解得一族特征曲线 $\varphi(x, y) = h$. 任取二元函数 $\psi(x, y)$, 使 $J = \frac{\partial(\varphi, \psi)}{\partial(x, y)} \neq 0$. 作变量代换

$$\xi = \varphi(x, y), \quad \eta = \psi(x, y),$$

新方程为

$$\frac{\partial^2 u}{\partial \eta^2} + \frac{1}{A_{22}} \left(B_1 \frac{\partial u}{\partial \xi} + B_2 \frac{\partial u}{\partial \eta} + C u \right) = 0, \quad (1.5.13)$$

称方程 (1.5.13) 为抛物型方程的标准形.

当 $\Delta < 0$ 时, 特征方程 (1.5.9) 只能在复数域内分解成两个一阶方程. 不妨设 $a_{11} \neq 0$, 相应的一阶方程为

$$\frac{dy}{dx} = \frac{a_{12} + i\sqrt{-\Delta}}{a_{11}} \quad \text{和} \quad \frac{dy}{dx} = \frac{a_{12} - i\sqrt{-\Delta}}{a_{11}},$$

此时, 不存在实特征线, 特征方程 (1.5.9) 的隐式通解为

$$\varphi(x, y) \pm i\psi(x, y) = h.$$

为避免引入复变量, 作变换

$$\begin{cases} \xi = \varphi(x, y), \\ \eta = \psi(x, y), \end{cases}$$

由定理 1.5.1 将 $z = \varphi(x, y) \pm i\psi(x, y)$ 代入方程 (1.5.8), 分别取其实、虚部, 可得 $A_{11} = A_{22}, A_{12} = 0$, 则有新方程

$$\frac{\partial^2 u}{\partial \xi^2} + \frac{\partial^2 u}{\partial \eta^2} + \frac{1}{A_{11}} \left(B_1 \frac{\partial u}{\partial \xi} + B_2 \frac{\partial u}{\partial \eta} + C u \right) = 0. \quad (1.5.14)$$

称方程 (1.5.14) 为椭圆型方程的标准形.

例 1.4.4 三维波动方程的初值问题

$$\begin{cases} \frac{\partial^2 u}{\partial t^2} = a^2 \Delta_3 u, & t > 0, r = \sqrt{x^2 + y^2 + z^2} > 0, \\ u|_{t=0} = \varphi(r), \quad \frac{\partial u}{\partial t}|_{t=0} = \psi(r). \end{cases} \quad (1.4.11)$$

解 由初始条件的球对称性, 可设未知函数 $u = u(t, r)$. 采用球坐标, 方程为

$$\frac{\partial^2 u}{\partial t^2} = a^2 \left(\frac{\partial^2 u}{\partial r^2} + \frac{2}{r} \frac{\partial u}{\partial r} \right).$$

作未知函数的代换

$$u(t, r) = e^{\alpha(r)} v(t, r),$$

其中, $\alpha(r)$ 待定, 目的是消去一阶导数项. 代入 u 的方程, 得 v 的方程

$$\frac{\partial^2 v}{\partial t^2} = a^2 \left\{ \frac{\partial^2 v}{\partial r^2} + \left[2\alpha'(r) + \frac{2}{r} \right] \frac{\partial v}{\partial r} + \left[\alpha''(r) + \alpha'(r)^2 + \frac{2}{r} \alpha'(r) \right] v \right\},$$

当 $\alpha(r) = -\ln r$, 即 $v = ru$ 时, 则为一维波动方程

$$\frac{\partial^2 v}{\partial t^2} = a^2 \frac{\partial^2 v}{\partial r^2}.$$

$$\delta(x) * f(x) = f(x),$$

$$\delta'(x) * f(x) = \delta(x) * f'(x) = f'(x),$$

$$\delta^{(n)}(x) * f(x) = \delta(x) * f^{(n)}(x) = f^{(n)}(x),$$

$$L(f(x) * g(x)) = (Lf) * g = f * Lg,$$

$$<\delta^{(n)}(x), \varphi(x)> \stackrel{\text{定义}}{=} (-1)^n <\delta(x), \varphi^{(n)}(x)> = (-1)^n \varphi^{(n)}(0), \forall \varphi(x) \in C_0^\infty(\mathbb{R})$$

例 1.4.3 一端固定半无界弦的自由振动

$$\begin{cases} \frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial x^2}, & t > 0, x > 0, \\ u(t, 0) = 0, \\ u(0, x) = \varphi(x), \quad u_t(0, x) = \psi(x). \end{cases} \quad (1.4.9)$$

分析 这里的初始条件 $\varphi(x), \psi(x)$ 仅在 $x > 0$ 有定义, 故不能直接应用达朗贝尔公式. 但由达朗贝尔公式 (1.4.6) 可知, 如果定义在整个实轴上的 $\varphi(x), \psi(x)$ 为奇函数, 则

$$u(t, 0) = \frac{1}{2}[\varphi(-at) + \varphi(at)] + \frac{1}{2a} \int_{-at}^{at} \psi(\xi) d\xi = 0.$$

如果 $\varphi(x), \psi(x)$ 是偶函数, 则

$$\frac{\partial u}{\partial x}(t, 0) = \frac{1}{2}[\varphi'(-at) + \varphi'(at)] + \frac{1}{2a} [\psi(at) - \psi(-at)] = 0.$$

因此, 可用延拓法将 (1.4.9) 式中的 $\varphi(x), \psi(x)$ 从 $x > 0$ 奇延拓到 $x < 0$, 再利用达朗贝尔公式, 求出的解必满足边界条件 $u(t, 0) = 0$.

解 作辅助函数

$$\varPhi(x) = \begin{cases} \varphi(x), & x \geq 0, \\ -\varphi(-x), & x < 0, \end{cases} \quad \Psi(x) = \begin{cases} \psi(x), & x \geq 0, \\ -\psi(-x), & x < 0. \end{cases}$$

由达朗贝尔公式得 (1.4.9) 式的解

$$\begin{aligned} u(t, x) &= \frac{1}{2}[\varPhi(x + at) + \varPhi(x - at)] + \frac{1}{2a} \int_{x-at}^{x+at} \Psi(\xi) d\xi \\ &= \begin{cases} \frac{1}{2}[\varphi(x + at) + \varphi(x - at)] + \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi) d\xi, & t \leq \frac{x}{a}, \\ \frac{1}{2}[\varphi(x + at) - \varphi(at - x)] + \frac{1}{2a} \int_{at-x}^{x+at} \psi(\xi) d\xi, & t > \frac{x}{a}. \end{cases} \end{aligned} \quad (1.4.10)$$

为理解此解的物理意义, 不妨设初速度 $\psi(\xi) = 0$. 当 $t \leq \frac{x}{a}$ 时, 端点的影响尚未传到 x 点, x 点的运动仍由初位移引起的左右行波 $\frac{1}{2}[\varphi(x + at) + \varphi(x - at)]$ 决定. 当 $t \geq \frac{x}{a}$ 时, 端点的影响已传到 x 点, x 点的运动由左行波 (入射波) $\frac{1}{2}\varphi(x + at)$ 和右行波 (反射波) $-\frac{1}{2}\varphi(at - x)$ 决定. 在端点 $x = 0$ 处, 入射波与反射波分别为 $\frac{1}{2}\varphi(at)$ 和 $-\frac{1}{2}\varphi(at)$, 故 $u(t, 0) = 0$.

类似地, 也可通过将 $\varphi(x), \psi(x)$ 作偶延拓求解端点自由的半无界弦的自由振

由一维波动方程的通解得三维波动方程的球面对称解

$$u(t, r) = \frac{1}{r}[f(r - at) + g(r + at)],$$

其中, $f(r - at)$ 为发散波, $g(r + at)$ 为会聚波, $\frac{1}{r}$ 为波形的衰减 ($r > 1$) 或扩张 ($r < 1$) 因子. 利用公式 (1.4.10) 可写出初值问题 (1.4.11) 式的解

$$u(t, r) = \begin{cases} \frac{1}{2r}[(r + at)\varphi(r + at) + (r - at)\varphi(r - at)] + \frac{1}{2ar} \int_{r-at}^{r+at} \xi \psi(\xi) d\xi, & t \leq \frac{r}{a}, \\ \frac{1}{2r}[(r + at)\varphi(r + at) - (at - r)\varphi(at - r)] + \frac{1}{2ar} \int_{at-r}^{r+at} \xi \psi(\xi) d\xi, & t > \frac{r}{a}. \end{cases} \quad (1.4.12)$$

行波解对研究波动问题很重要, 对较复杂的方程, 寻找其行波解常常是研究问题的第一步. 例如, 设 KdV 方程 (1.1.10)

$$(P45)12(1) \quad (y+z)\frac{\partial u}{\partial x} + (z+x)\frac{\partial u}{\partial y} + (x+y)\frac{\partial u}{\partial z} = 0.$$

提示: 特征方程为 $\frac{dx}{y+z} = \frac{dy}{z+x} = \frac{dz}{x+y}$. $\frac{dx}{y+z} \neq d\left(\frac{x}{y+z}\right)$,

注: 由 $\frac{dx}{y+z} = \frac{dy}{z+x}$ 或 $\frac{dy}{z+x} = \frac{dz}{x+y}$ 都无法得到首次积分.

$$\frac{dx}{y+z} = \frac{dz}{x+y} = \frac{dx-dz}{(y+z)-(x+y)} = -\frac{d(z-x)}{z-x}.$$

$$\text{同理 } \frac{dy}{z+x} = \frac{dz}{x+y} = \frac{dy-dz}{(z+x)-(x+y)} = -\frac{d(y-z)}{y-z},$$

另, $\frac{dx}{y+z} = \frac{dy}{z+x} = \frac{dz}{x+y} = \frac{dx+dy+dz}{(y+z)+(z+x)+(x+y)} = \frac{d(x+y+z)}{2(x+y+z)}$. 因此

$$-\frac{d(z-x)}{z-x} = -\frac{d(y-z)}{y-z} = \frac{d(x+y+z)}{2(x+y+z)}. \text{ 由它求出两个首次积分.}$$

$$\text{由 } \frac{d(z-x)}{z-x} - \frac{d(y-z)}{y-z} = 0 \text{ 得 } \ln \frac{z-x}{y-z} = h, \quad \frac{z-x}{y-z} = e^h \neq 0.$$

$$\text{由 } \frac{d(y-z)}{y-z} + \frac{d(x+y+z)}{2(x+y+z)} = 0 \text{ 得 } \ln(y-z)\sqrt{x+y+z} = h_2,$$

$$(y-z)^2(x+y+z) = e^{2h_2} \neq 0. \quad \dots \text{(同学们自己补充完整).} \#$$

例 2.2.3 求解扇形域上的 Dirichlet 问题

$$\begin{cases} \Delta_2 u = 0, & 1 < r < e, 0 < \theta < \frac{\pi}{2}, \\ u|_{r=1} = u|_{r=e} = 0, \\ u|_{\theta=0} = 0, \quad u|_{\theta=\frac{\pi}{2}} = g(r), \end{cases} \quad (2.2.17)$$

这里, (r, θ) 为极坐标, e 为自然对数的底数.

解 极坐标下, 方程为

$$r^2 \frac{\partial^2 u}{\partial r^2} + r \frac{\partial u}{\partial r} + \frac{\partial^2 u}{\partial \theta^2} = 0,$$

设 $u(r, \theta) = R(r)\Theta(\theta)$, 代入方程和关于 r 的齐次边界条件, 分离变量得固有值问题

$$\begin{cases} r^2 R''(r) + rR'(r) + \lambda R(r) = 0, & 1 < r < e, \\ R(1) = R(e) = 0 \end{cases} \quad (2.2.18)$$

及常微分方程

$$\Theta''(\theta) - \lambda \Theta(\theta) = 0.$$

固有值问题中的方程是变系数二阶线性方程, 可化为 S-L 型

$$[rR'(r)]' + \lambda \frac{1}{r} R(r) = 0,$$

这里, $k(r) = r$, $q(r) \equiv 0$, $\rho(r) = \frac{1}{r}$. 由 S-L 定理知 $\lambda > 0$.

二(14分)求解定解问题:

$$\begin{cases} u_{tt} = a^2 u_{xx} + 1, & (0 < x < l, t > 0) \\ u(t, 0) = 0, \quad u_x(t, l) = 0, \\ u|_{t=0} = \varphi(x), \quad u_t|_{t=0} = \psi(x), \end{cases}$$

二. 设 $u = u_1 + u_2$, 先解 u_1 (齐次问题)

固有值和固有函数为:

$$\lambda_n = \left[\frac{(2n+1)\pi}{2l} \right]^2, \quad X_n(x) = \sin \frac{(2n+1)\pi x}{2l} \quad n = 0, 1, \dots \quad (7 \text{ 分})$$

设级数解为

$$u_1(t, x) = \sum_{n=0}^{+\infty} [C_n \cos \frac{(2n+1)\pi at}{2l} + D_n \sin \frac{(2n+1)\pi at}{2l}] \sin \frac{(2n+1)\pi x}{2l}$$

由初始条件得

$$C_n = \frac{2}{l} \int_0^l \varphi(\xi) \sin \frac{(2n+1)\pi \xi}{2l} d\xi$$

$$D_n = \frac{4}{(2l+1)\pi a} \int_0^l \psi(\xi) \sin \frac{(2n+1)\pi \xi}{2l} d\xi \quad (10 \text{ 分})$$

对于 u_2 (非齐次问题)

$$1 = \sum_{n=0}^{+\infty} f_n \sin \frac{(2n+1)\pi x}{2l}, \quad f_n = \frac{4}{(2n+1)\pi}$$

$R(r)$ 的方程是欧拉 (Euler) 方程, 作变量代换 $r = e^t$, 记 $y(t) = R(e^t)$, 则变系数方程的固有值问题 (2.2.18) 式转化为最简 S-L 型方程固有值问题

$$\begin{cases} y''(t) + \lambda y = 0, & 0 < t < 1, \\ y(0) = y(1) = 0. \end{cases}$$

即得固有值

$$\lambda_n = (n\pi)^2, \quad n = 1, 2, \dots$$

及固有函数

$$y_n(t) = \sin n\pi t,$$

亦即

$$R_n(r) = \sin(n\pi \ln r).$$

相应地

$$\Theta_n(\theta) = A_n \cosh n\pi \theta + B_n \sinh n\pi \theta.$$

设

$$u(r, \theta) = \sum_{n=1}^{+\infty} (A_n \cosh n\pi \theta + B_n \sinh n\pi \theta) \sin(n\pi \ln r),$$

代入关于 θ 的边界条件, 得

$$u|_{\theta=0} = \sum_{n=1}^{+\infty} A_n \sin(n\pi \ln r) = 0,$$

$$u|_{\theta=\frac{\pi}{2}} = \sum_{n=1}^{+\infty} B_n \sinh \frac{n\pi^2}{2} \sin(n\pi \ln r) = g(r),$$

这里, $\{\sin(n\pi \ln r), n = 1, 2, \dots\}$ 是区间 $[1, e]$ 上加权函数 $\rho(r) = \frac{1}{r}$ 的完备正交函数系, 故

$$\begin{aligned} A_n &= 0, \\ B_n &= \frac{1}{\sinh \frac{n\pi^2}{2}} \cdot \int_1^e g(r) \sin(n\pi \ln r) \frac{1}{r} dr \\ &= \frac{2}{\sinh \frac{n\pi^2}{2}} \int_0^1 g(e^t) \sin(n\pi t) dt. \end{aligned}$$

卷积写开

$$u_2 = \sum_{n=0}^{+\infty} T_n(t) \sin \frac{(2n+1)\pi x}{2l}$$

$$T_n(t) \text{ 满足 } T'' + \lambda_n a^2 T = \frac{4}{(2n+1)\pi}, \quad T(0) = T'(0) = 0$$

$$T_n(t) = \frac{16l^2}{(2n+1)^3 a^2 \pi^3} - \frac{16l^2}{(2n+1)^3 a^2 \pi^3} \cos \frac{(2n+1)\pi at}{2l} \quad (14 \text{ 分})$$

最后

$$u = u_1 + u_2$$

本题也可以用特解法和齐次化原理法求解
